
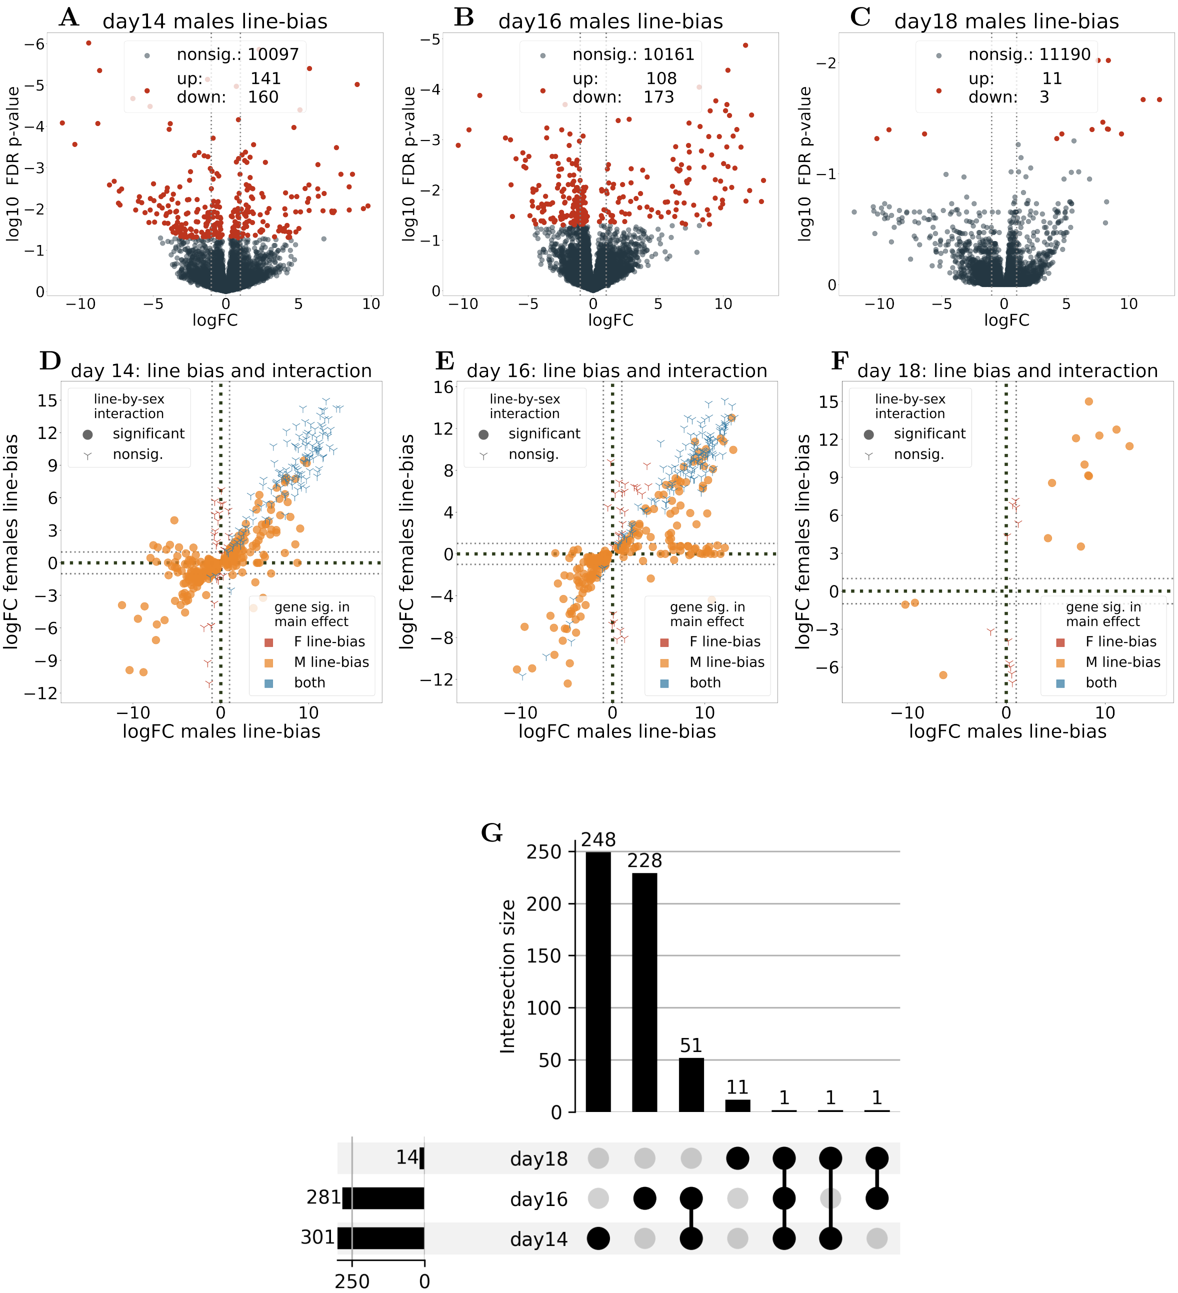

Figure 1: **Line-biased genes in males**. (**A**, **B**, **C**): Genes significantly differentially expressed in each developmental timepoint (FDR-p < 0.05), genes that are line-biased in females are excluded. Figure legend shows numbers of nonsignificant (nonsig.) genes, and genes that are significantly up- or downregulated, with upregulated genes being biased towards the large male haplotype in the large-small contrast. (**D**, **E**, **F**): log2FC of genes that show significant line-bias in male samples, female samples or both. All genes that are exclusively male-biased (yellow) are also significant in the line-by-sex interaction. (**G**): UpSet plot showing the overlap of line-significant genes identified in A-F.

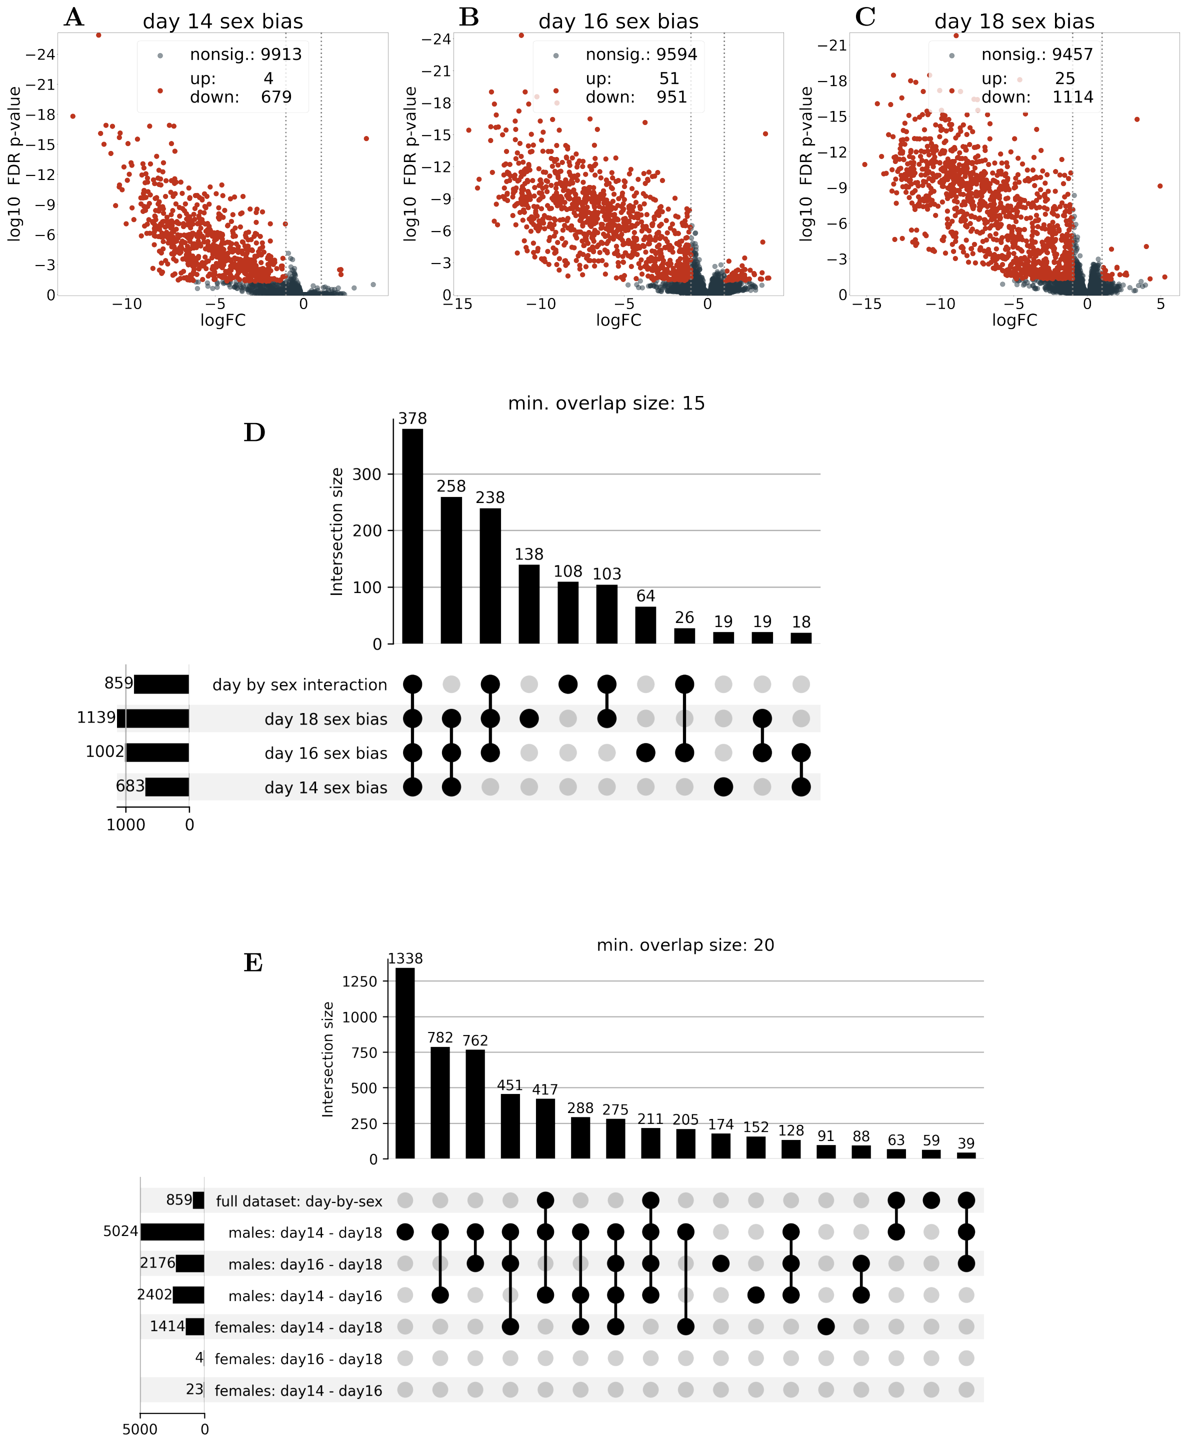

Figure 2: **Sex bias across developmental stages**. (**A**, **B**, **C**): Genes that are significantly sex-biased in each developmental time point (Y-haplotype line modelled as fixed effect). Upregulated genes are female-biased in the female-male contrast. (**D**, **E**): UpSet plots showing the overlap of genes that are significant in the day-by-sex interaction overlapping with genes that are sex biased on any time point in the full dataset (**D**) or time-biased in the day-split data (**E**). Only intersections with at least 15 or 20 genes are shown.

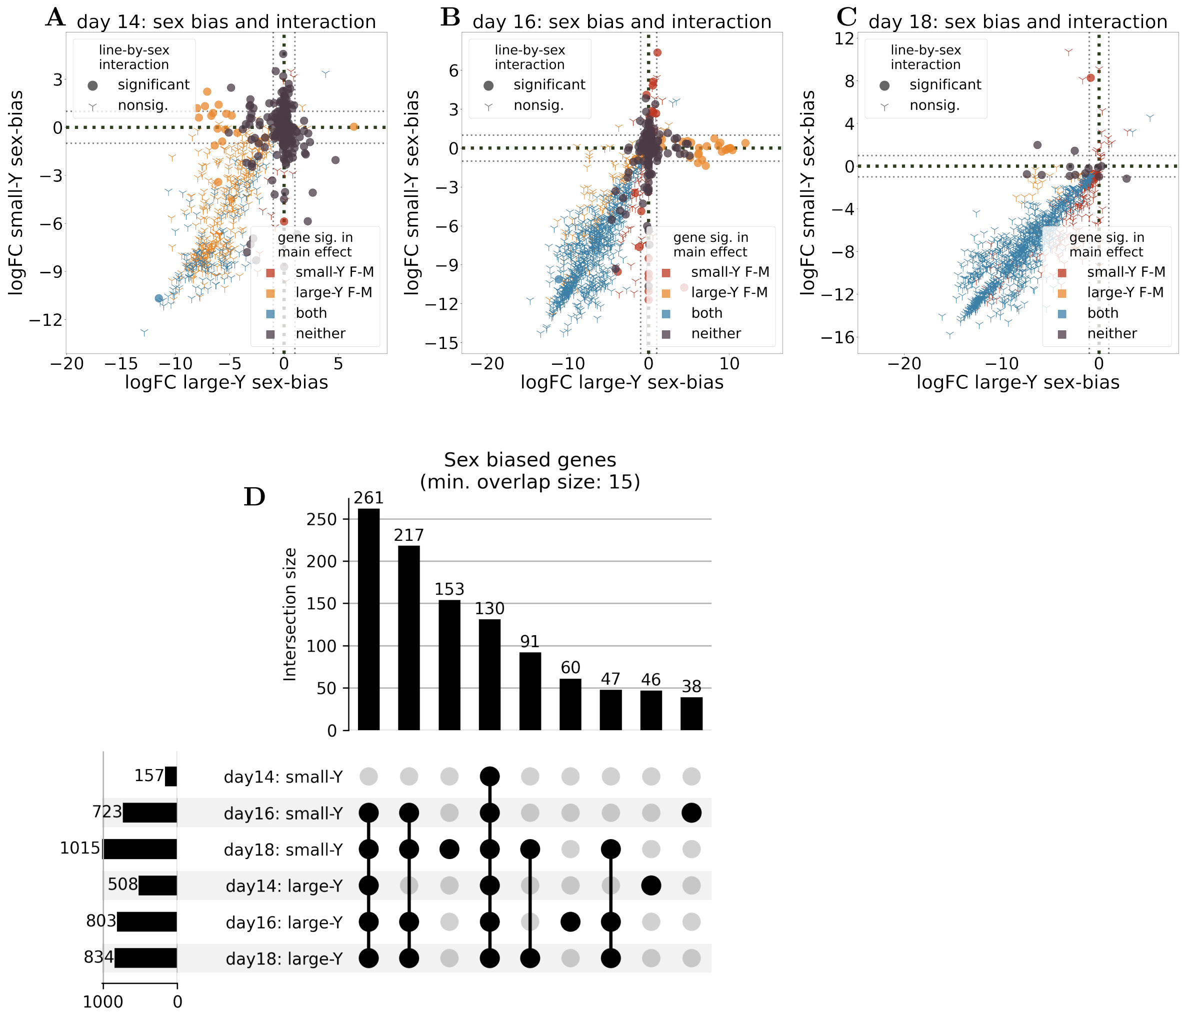

Figure 3: **Sex bias across developmental stages**. (**A**, **B**, **C**): Day-split data showing sex bias of large and small male haplotype lines in each day. Genes that are significant in the sex-by-line interaction of the individual day are highlighted. (**D**): UpSet plot showing the overlap of sex biased genes
