

Figure 1: Line-biased genes in males. (A, B, C): Genes significantly differentially expressed in each developmental timepoint (FDR- $p < 0.05$), genes that are line-biased in females are excluded. Figure legend shows numbers of nonsignificant (nonsig.) genes, and genes that are significantly up- or downregulated. (D, E, F): $\log_2$ FC of genes that show significant line-bias in male samples, female samples or both. All genes that are exclusively male-biased (yellow) are also significant in the line-by-sex interaction. (G): UpSet plot showing the overlap of line-significant genes identified in A-F.

Figure 2: **Sex bias across developmental stages.** (A, B, C): Genes that are significantly sex-biased in each developmental time point (Y-haplotype line modelled as fixed effect). (D): UpSet plot showing the overlap of genes that are significantly day-biased in males or in females with each other and the genes that are significant in the day-by-sex interaction in the full dataset. Only intersections with at least 20 genes are shown.
