

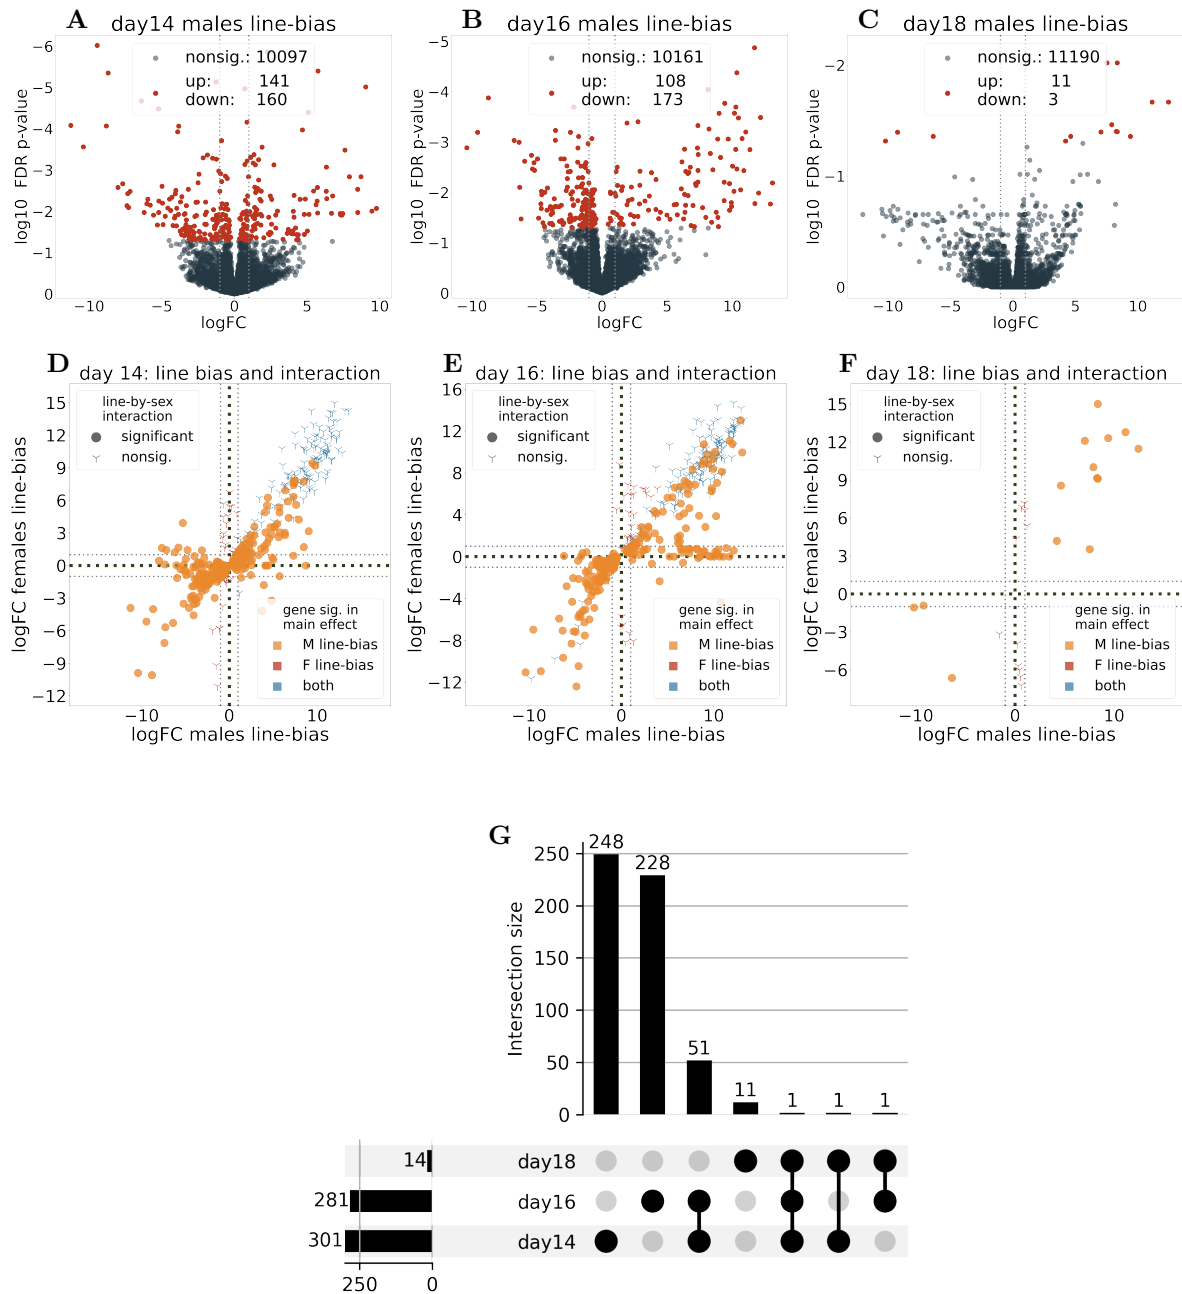

Figure 1: Line-biased genes in males. (A, B, C): Genes significantly differentially expressed in each developmental timepoint (FDR- $p < 0.05$), genes that are line-biased in females are excluded. Figure legend shows numbers of nonsignificant (nonsig.) genes, and genes that are significantly up- or downregulated. (D, E, F): $\log_2FC$ of genes that show significant line-bias in male samples, female samples or both. All genes that are exclusively male-biased (yellow) are also significant in the line-by-sex interaction. (G): UpSet plot showing the overlap of line-significant genes identified in A-F.

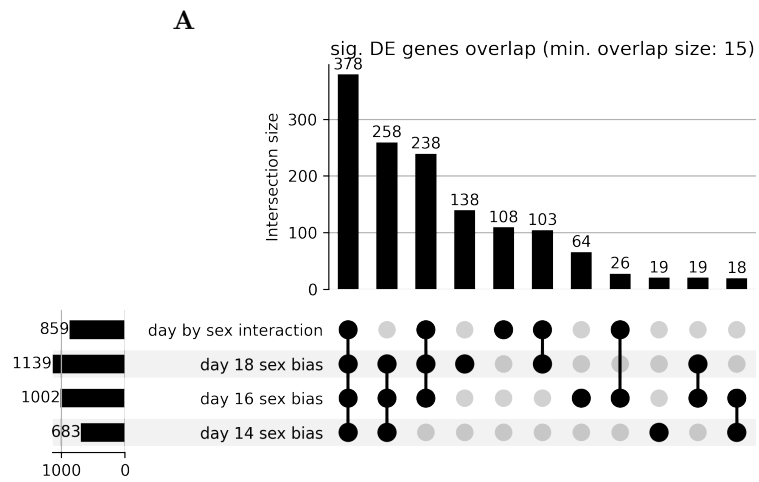

Figure 2: **Sex bias across developmental stages.** (A): UpSet plot showing the overlap of significantly sex-biased genes during different time points with each other and the genes that are significant in the day-by-sex interaction.
